Load Balancer and Auto Scaling.

Scenario – 1

An development company wants to create an webservice on AWS. On a regular day they expect **1000** requests to their webservers.

But on the peak days it goes upto **10000** requests.

Developer of the application has mentioned that an Single webserver of **"X"** size can handle **1200** requests at it peak, but the recommended value is **80%** of the Load on each Webserver.

Create an Load Balancer with redundancy between 3 Availability Zones.

And then configure the pre-loaded webserver image for the Scaling under the Load Balancer.

Make sure the Scaling of the "VM" happen at 70% of the avg load and increase it by "1" at a time.

The scaling policy should be able to handle the PEAK days load as well.

Example for creating Webserver.

Sudo yum install httpd

Sudo service httpd start

Sudo chkconfig httpd on

Sudo vi /var/www/html/index.html

Press "I" to insert the below text

<html>

<a> This is just a FUN PAGE </a>

</html>

Press 'esc"

Type ":qw" and "Enter"

The webserver is ready.
